# Simple Eclipsing Binary

Theoretically, we can describe a star by five quantities: Mass, Radius, Temperature, Chemical Composition, Time (age).

# Simple Eclipsing Binary

Theoretically, we can describe a star by five quantities: Mass, Radius, Temperature, Chemical Composition, Time (age).

**Figure:** The (ideal) light curve of an eclipsing binary (Ostlie, 1996)

# $\epsilon$ Aurigae

The Light Curve of  $\epsilon$  Aurigae suggests it is an eclipsing binary, except:

- ▶ The Eclipse happens once every 27 years
- ▶ The Eclipse lasts for two years
- ▶ The Spectrum looks like a  $15 M_{\odot}$  F-Super giant star.
- ▶ No Significant evidence for the companion star.
- ▶ So, what is causing the eclipse?

# $\epsilon$ Aurigae

# Astronomical Nomenclature

## Angular Measurements

- ▶ 1 Radian =  $180/\pi \approx 57.3$  degrees
- ▶ 1 Degree = 60 arc-minutes =  $60^2$  arc-seconds
- ▶ 1 arc-second  $\approx 5 * 10^{-6}$  rad = 5 micro-radians
- ▶ 1 milli arc-second  $\approx 5$  nano-radians

Astronomers also speak of the angular resolution of a telescope.  
Often this is defined by the Rayleigh Diffraction Criterion:

- ▶  $\theta = 1.22 \frac{\lambda}{D}$

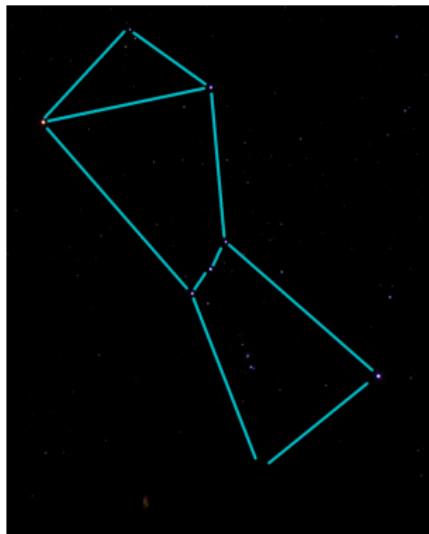

where  $\lambda$  is the wavelength and  $D$  is the diameter of the telescope.

# Why Build an Interferometer?

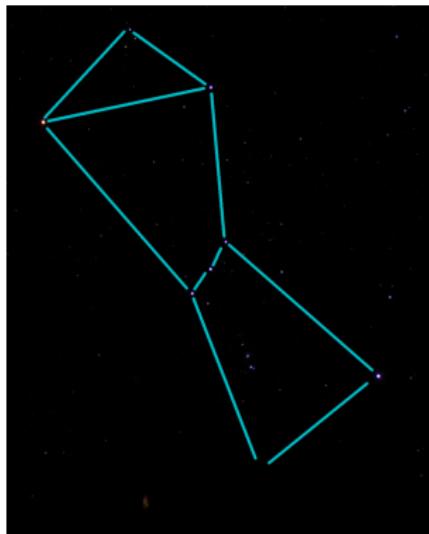

**Figure:** Betelgeuse ( $\alpha$  Orionis),  
has an angular diameter of 223  
nrad (46 mas).

# Why Build an Interferometer?

**Figure:** Betelgeuse ( $\alpha$  Orionis), has an angular diameter of 223 nrad (46 mas).

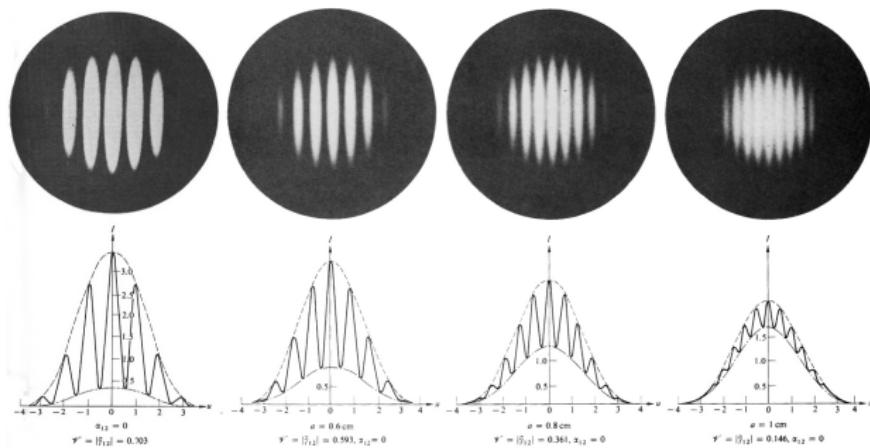

- ▶ The Largest Telescopes Lack Sufficient Resolution
  - ▶ Keck Telescopes: 10 m
  - ▶ 268 nrad (55 mas)
- ▶ Large Mirrored Telescopes are expensive

# The Michelson Interferometer

**Figure:** Schematic Drawings of a Michelson Interferometer (Hecht, 2002)

# Fringes

**Figure:** Fringes as seen by an Interferometer (Hecht, 2002)

Visibility Squared:

$$V^2 = \left( \frac{I_{max} - I_{min}}{I_{max} + I_{min}} \right)^2$$

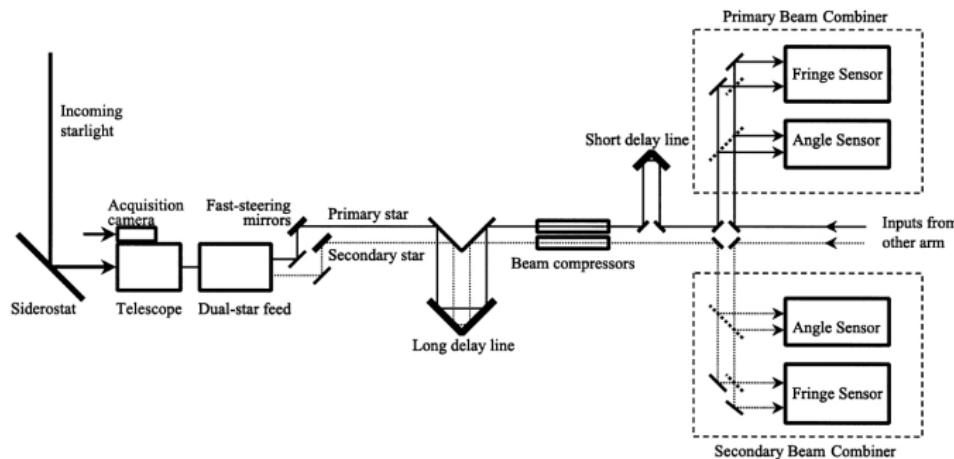

# Palomar Testbed Interferometer

**Figure:** Aerial View of PTI and the 200" Palomar Telescope  
(Gerald van Belle)

- ▶ PTI Operated by the Michelson Science Center on behalf of CalTech and NASA-JPL
- ▶ Maximum Baseline, 110 meters
- ▶ Resolution 8.1 - 10.5 nrads (1.67 - 2.18 mas)

# PTI Schematic Drawing

**Figure:** Schematic Drawing of PTI (Colavita, 1999)

# PTI Schematic Drawing

# Model Selection

- ▶ Uniform Disk
- ▶ Limb-Darkened
- ▶ Others

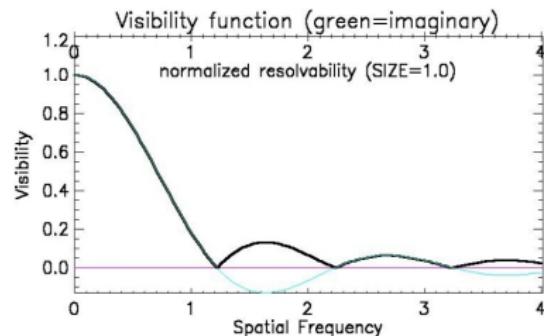

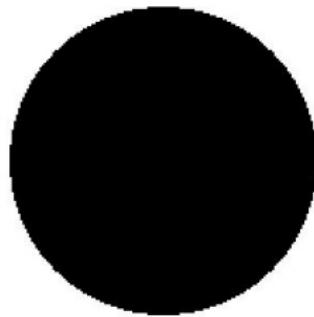

Figure: Disk Models (Meisner, J.)

# Model Selection

- ▶ Uniform Disk
- ▶ Limb-Darkened
- ▶ Others

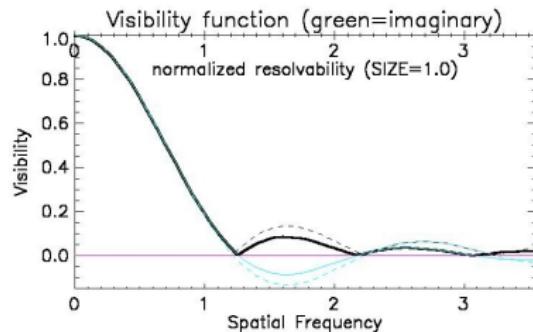

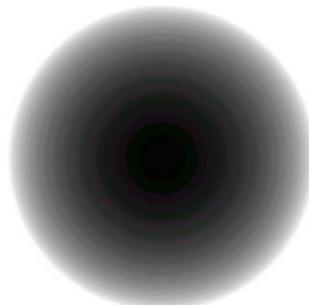

Figure: Disk Models (Meisner, J.)

# Model Selection

- ▶ Uniform Disk
- ▶ Limb-Darkened
- ▶ Others
- ▶ Uniform Disk with a hole
- ▶ Ellipse
- ▶ Gaussian (with or without a hole)
- ▶ Binary Star (with or without a transit)
- ▶ Central "Hotspot"

# Uniform Disk

Visibility squared readings from the interferometer are matched to an angle using a model. In our case, we considered the uniform disk model:

$$V^2(\theta, B, \lambda) = \frac{(2 * J_1(\pi\theta B/\lambda))^2}{(\pi\theta B/\lambda)} \quad (1)$$

where  $B$  is the projected baseline and  $J_1(x)$  is a Bessel function of the first kind.

## Bessel Function Approximation

Unfortunately, my version of Excel does not have a Bessel function built-in, so I wrote one. Using Arfken's definition:

$$J_{\nu}(x) = \sum_{s=0}^{\infty} \frac{(-1)^s}{s!(s+\nu)!} \left(\frac{x}{2}\right)^{\nu+2s} \quad (2)$$

I wrote a macro that takes the first n-terms of the expansion:

$$J_{\nu}(n, x) = \sum_{s=0}^n \frac{(-1)^s}{s!(s+\nu)!} \left(\frac{x}{2}\right)^{\nu+2s} \quad (3)$$

I elected to use the first seven terms from the expansion so that the maximum error that could be contributed by the next term in the series was below  $5 \times 10^{-9}$ .

# The Lookup Table

Solving for the angular diameter,  $\theta$ , in the visibility squared equation is not easily done:

$$\frac{(2 * J_1(\pi\theta B/\lambda))^2}{(\pi\theta B/\lambda)} = V^2$$

Therefore I elected to create a lookup table that takes values of  $(\pi\theta B/\lambda)$  between  $\approx 0.45$  and  $\approx 2.55$  in  $3.2 \times 10^{-5}$  increments.

- ▶ Produces  $V^2$  values between 0.14 and 0.95 in  $2 \times 10^{-5}$  increments.
- ▶ Consists of 65534 rows

# Obtaining Results

The lookup table facilitates our analysis by allowing us to match the  $V^2$  values from PTI with a corresponding value of  $(\pi\theta B/\lambda)$ . After that, it's simply algebra:

$$\theta = \frac{\lambda X}{\pi B} \quad (4)$$

Where  $X$  is the (numerical) value for  $(\pi\theta B/\lambda)$  in the lookup table.

# Results

# Future Observations

When we go back, what will we look for?

- ▶  $\epsilon$  Aurigae exhibits large changes in brightness over very short time periods. Is this a form of pulsation? Can it be detected by PTI?
- ▶ Is this star really a F-supergiant? Could it be a Post Asymptotic Giant Branch Star (AGB)?
- ▶ More Pre-eclipse Data. How does the system change before and after eclipse?
- ▶ How does the angular diameter change as the disk passes? Does the disk divide the star in two?

# Future Observations
